Abstract The National Oceanic and Atmospheric Administration has developed a tsunami forecast model for Adak, Alaska as part of an effort to provide tsunami forecasts for United States coastal communities. The tsunami forecast model relies on the Method of Splitting Tsunami numerical code for real-time simulations. Parallel to the tsunami forecast model, a reference inundation model was also developed at higher resolution and with larger space coverage. A series of historical events were simulated with the forecast and reference models to test them for numerical accuracy. The two models are in fair agreement with each other, as well as with available tsunami records at Adak tide gauge. A number of synthetic events, including extreme scenarios, were also simulated to test the models for stability and mutual consistency. The forecast model is capable of completing a 4-hr simulation within 3.6 min of CPU time, as tested on a single Intel Xeon processor at 3.6 GHz, which meets the runtime requirement for forecast models.

1 Background and Objectives

The National Oceanic and Atmospheric Administration (NOAA) Center for Tsunami Research (NCTR) at the NOAA Pacific Marine Environmental Laboratory (PMEL) has developed a tsunami forecasting system for operational use by NOAA's two tsunami warning centers located in Hawaii and Alaska (Titov et al., 2005). The system is designed to efficiently provide basin-wide warning of approaching tsunami waves accurately and quickly. The system, termed Short-term Inundation Forecast of Tsunamis (SIFT), combines realtime tsunami event data with numerical models to produce estimates of tsunami wave arrival times and amplitudes at a coastal community of interest. The SIFT system integrates several key components: deep-ocean observations of tsunamis in real time, a basin-wide precomputed propagation database of water level and flow velocities based on potential seismic unit sources, an inversion algorithm to refine the tsunami source based on deep-ocean observations during an event, and high-resolution tsunami inundation forecast models.

The town of Adak, population 326 (United States Census Bureau, 2012), is located on the northeast side of Adak Island. The island is part of the Andreanof Islands group of the Aleutian Islands. Adak is the southernmost population center in Alaska, and the largest population center in the Aleutian Islands west of Unalaska (Figure 1). There are no other towns or settlements on Adak Island outside of the town of Adak (Figure 2). The town's harbor, Sweeper Cove, is well-protected from weather, making it one of the safest harbors in the Aleutian Islands (United States Coast Pilot, 2010).

During World War II, Adak was a major United States Navy supply and logistics center, and was occupied by over 30,000 military personnel in 1944. After the end of the war, the naval air station operated on the island, with resident populations up to 6,000, until its closure in 1997. As a result of this military history, the town has extensive infrastructure, including two large paved airport runways and multiple deep-water ship berthing piers (Figure 3). After the base closure, most property and facilities within the town, as well as much of the northern part of the island, were transferred from the United States government to Aleut Corporation, an Alaska Native Regional Corporation (Sepez et al., 2005). Lands in the southern portion of Adak Island are part of the Alaska Maritime National Wildlife Refuge, managed by the U.S. Fish and Wildlife Service.

Adak is subject to hazards due to tsunamis originating in the nearby Alaska-Aleutian Subduction Zone, as well as other regions in the Pacific basin. This report documents the development of a tsunami inundation forecast model covering the community of Adak, Alaska. This operational forecast model is designed for integration into the SIFT system. The objective of this system is to provide NOAA's tsunami warning centers with the capability of accurate and timely tsunami forecasts, which helps the under-threat communities to respond appropriately.

2 Forecast Method

A high-resolution inundation model was used as the basis for the development of a tsunami forecast model to operationally provide an estimate of wave arrival time, wave height, and inundation at Adak following tsunami generation. All tsunami forecast models are run in real time while a tsunami is propagating across the open ocean. The Adak model was designed and tested to perform under stringent time constraints given that time is generally the single limiting factor in saving lives and property. The goal of this work is to maximize the length of time that the community of Adak has to react to a tsunami threat by providing accurate information quickly to emergency managers and other officials responsible for the community and infrastructure.

The general tsunami forecast model, based on the Method of Splitting Tsunami (MOST), is used in the tsunami inundation and forecasting system to provide real-time tsunami forecasts at selected coastal communities. The model runs in minutes employing high-resolution grids constructed based on the bathymetric and topographic data provided by the National Geophysical Data Center (NGDC). MOST is a suite of numerical simulation codes capable of simulating three processes of tsunami evolution: generation due to earthquake, transoceanic propagation, and inundation of dry land. The model has been extensively tested against a number of laboratory experiments and benchmarks (Synolakis et al., 2008) and was successfully used for simulations of many historical tsunami events. The main objective of a forecast model is to provide an accurate, yet rapid, estimate of wave arrival time, wave height, and inundation in the minutes following a tsunami event. Titov and González (1997) describe the technical aspects of inundation model development, stability, testing, and robustness, and Tang et al. (2009) provide detailed forecast methodology.

A basin-wide database of pre-computed water elevations and flow velocities for unit sources covering worldwide subduction zones has been generated to expedite forecasts (Gica et al., 2008). As the tsunami wave propagates across the ocean and successively reaches tsunameter observation sites, which are strategically positioned in areas with great potential for tsunami generation, recorded sea level is ingested into the tsunami forecast application in near real-time and incorporated into an inversion algorithm to produce an improved estimate of the tsunami source. A linear combination of the pre-computed database is then performed based on this tsunami source.

Accurate forecasting of the tsunami impact on a coastal community largely relies on the accuracy of bathymetry and topography in addition to the numerical computation. The high spatial and temporal grid resolution necessary for modeling accuracy poses a challenge in the run-time requirement for real-time forecasts. Each forecast model consists of three nested grids (A, B, and C), each of which is successively finer in resolution, moving from offshore to onshore. Within the finest resolution grid in the set of three (C grid), the nearshore details are resolved to the point that model output can be directly compared with tide gauge observations. The forecast model utilizes the most recent bathymetry and topography data available to reproduce the correct wave dynamics during the inundation computation. Forecast models, including the Adak model, are constructed for at-risk coastal communities in the Pacific and Atlantic Oceans. Previous and present development of forecast models in the Pacific (Titov et al., 2005; Tang et al., 2008; Wei et al., 2008; Titov, 2009) has validated the accuracy and efficiency of each forecast model currently implemented in the real-time tsunami forecast system.

3 Model Development

This section describes the tsunami model created for Adak, including background on the region, its tsunami event history, input data sources, and the process of model grid develop-

ment.

3.1 Forecast area

Adak city sits on a low-lying flat by Kuluk Bay on the northern part of Adak Island. Like other islands in the Aleutian archipelago, Adak Island is of volcanic origin. The island is comprised of a deeply glaciated southern area and a mountainous northern area. Most of the northern part was covered by glacial ice during the Pleistocene time (Coats, 1956). On the southern part, scattered small glacial deposits were also discovered despite that large glacial remnants may have been dumped into the sea or covered by ash layers in subsequent volcanic activities (Fraser and Snyder, 1959). Glacier erosion has heavily jagged the island's coastline, forming several fjords and bays.

The Adak Island is located near the edge of North America Plate. South of the island, the Pacific Plate is subducting under the North America Plate along the Alaska-Aleutian Trench. As a result, this area is very active seismically and has great potential for tsunami generation. Offshore of Adak Island, seabed drops sharply to the deep ocean floor. For example, water depth increases to more than 1000 m in less than 5 km north of the island. This configuration is very efficient to propagate tsunami energy from open ocean to the island's coastline.

3.2 Event history and records

Tsunamis have long been a known hazard in the Aleutians, including Adak. There is evidence of the destruction of an Aleut village on the west side of the island 3000 years B.P. (Fraser and Snyder, 1959). The risk of tsunamis may have been a factor in the location of early indigenous settlements on the more protected Bering Sea side of the islands, instead of on the open Pacific Ocean coast (McCartney and Veltre, 1999).

The NOAA National Ocean Service (NOS) tide gauge at Adak was established in August 1943, and has recorded most of the significant Pacific basin tsunamis since that time. The tide station is the westernmost station operated by NOS in Alaska. The National Tsunami Warning Center (West Coast and Alaska Tsunami Warning Center by 1 October 2013) operates two tide stations further west, at Amchitka and Shemya. Sweeper Cove, Adak's main harbor, is protected by a breakwater extending in a southerly direction from the north side of the harbor. The tide station is located at 176.6347°W 51.8617°N, near the midpoint of the harbor's Pier 3 (Figure 4). Water depths near the tide gauge are approximately 12 m below mean high water.

Table 1 summarizes the historic events used for testing the model at Adak. Details of events particularly notable to Adak's tsunami history are described here. Adak was the first coastal tide station to record waves for several major tsunamis occurring near the Andreanof Islands, illustrating its value for forecasting purposes.

The 9 March 1957 Andreanof earthquake (Mw 8.6) is the largest recorded seismic event along the subduction zone immediately adjacent to the Andreanof Islands (Johnson et al., 1994), and is the largest tsunami event recorded at Adak in terms of wave amplitude. A 1.91-m amplitude wave (12.5 feet, peak-to-trough) hit Adak's Sweeper Cove, causing substantial damage. Great Sitkin Island's Sand Bay, 37 km east-northeast of Adak across Sitkin Sound, saw a 4-m amplitude wave (Lander, 1996). No tide gauge record from Adak exists for this event, presumably because the tide gauge equipment was destroyed by waves.

The 28 March 1964 Gulf of Alaska earthquake (Mw 9.2) and tsunami caused extensive damage in south-central Alaska, as well as elsewhere in the Pacific, but produced a modest 0.3-m amplitude wave at Adak, causing no recorded damage (Lander, 1996). The source model used for testing has been previously used by other hazard assessment studies around the Pacific (Tang et al., 2006).

The 7 May 1986 Andreanof Islands earthquake (Mw 8.0) was the largest earthquake along the subduction zone adjacent to Adak to occur since 1957. It produced a 0.88-m amplitude wave at Adak, arriving within 18 min after the event, making this the closest event to Adak to have been recorded by the tide gauge (Lander, 1996). Therefore, this event provides a valuable case for testing the model's performance with near-field events. The source model used for testing this event was derived from the source parameters developed by Hwang and Kanamori (1986), the same source parameters used for a previous modeling work of this event at Adak (Kowalik and Whitmore, 1991).

Just over ten years after the 1986 event, the 10 June 1996 Andreanof earthquake (Mw 7.9) along the subduction zone immediately adjacent to Adak produced a tsunami recorded throughout the Pacific, including at deep-ocean bottom-pressure recorders deployed in the Aleutians and along the United States West Coast (Eble et al., 1997). The tide gauge at Adak was the first onshore tide gauge to record the tsunami waves, with a non-destructive 0.5-m wave arriving approximately ten minutes after the earthquake.

Of the major Pacific basin tsunamis to occur since 2000, none have produced substantial waves at Adak. The 15 November 2006 Kuril earthquake (Mw 8.3) and tsunami produced 20-cm amplitude waves, and the 27 February 2010 Chile earthquake (Mw 8.8) produced 38-cm amplitude waves, the largest tsunami recorded at Adak since 1996.

3.3 Bathymetric grid and model setup

Forecast of tsunami propagation and inundation is through real-time simulations in three telescoped grids. The basis for the development of these grids is high-resolution digital elevation models (DEMs). From these DEMs, three high-resolution "reference" elevation grids are first constructed for the development of a high-resolution reference model. From this reference model, an "optimized" model at lower resolution is constructed. This process reduces the model runtime to within an operationally specified period, which is 10 min for a 4-hr simulation. This operationally developed model is referred to as the optimized tsunami forecast model, or simply the "forecast model".

The accuracy of a forecast model highly depends on the accuracy of bathymetry and topography. The present forecast model is based on the DEMs developed by NCTR and NGDC, and we consider them to be an adequate representation of the local topography and bathymetry. As new DEMs become available, forecast models will be updated and report updates will be posted at "http://nctr.pmel.noaa.gov/forecast_reports".

A one-arc-second (approximately 30 m) cell size grid covering Adak and nearby islands (Carignan et al., 2009) provided source material for the higher-resolution (B and C) grids. This combined bathymetric/topographic grid was developed by NGDC under contract from NCTR specifically for tsunami modeling. The bathymetric surface is derived primarily from NOS surveys, except in deep-water areas where some research multibeam survey results were available, and some limited areas where soundings from electronic charts were incorporated. Topographic data was derived primarily from the NASA Shuttle Radar Topography Mission (SRTM) global dataset, enhanced in several areas with individual data points from other data sources. Vertical elevations in the grid are in meters above/below mean high water (MHW). Thus, this is the vertical datum at which the model runs. The horizontal datum is World Geodetic System 1984 (WGS 84).

Outside of the area covered by the Adak grid, the model grids were derived from NGDC's ETOPO1 global dataset (Amante and Eakins, 2009). Bathymetry in the Adak area in this dataset is primarily estimated from satellite altimetry readings. This dataset was resampled to the resolution of the outermost (A) model grids and mosaicked with the Adak dataset.

Three reference model grids and three forecast model grids were created by cropping and resampling these source grids (Figure 5). Table 2 contains the details of the model grid extents, grid node spacing, and model settings.

Broadly, the outermost (A) grid's role is to model wave dynamics as the tsunami transitions from propagation in the deep open ocean into the shallower Andreanof region. The southern extent of the high-resolution reference model was set to include the adjacent Aleutian Trench, the entire Andreanof Islands archipelago, and the wide adjacent Amchitka and Amutka Passes.

Experimentation with the model extents showed that excluding the deep water of the Aleutian Trench from the grid had little impact on modeled waves at Adak, indicating that wave dynamics in the deep water are well-described by the pre-computed propagation database. Thus, the southern extent of the forecast model could be set substantially further north. This change not only reduces the number of nodes in the forecast grid, but also reduces the maximum depth in the grid from 7725 m (reference model) to 6035 m (forecast model), allowing a longer model timestep that still satisfies the Courant-Friedrichs-Lewy (CFL) condition.

The intermediate (B) grid covers the island of Adak and several smaller outlying islands, modeling wave dynamics as the tsunami travels along the coastline and through the several narrow passes between islands. The complexity of these passages constrained the development of the forecast grid. The innermost (C) grid covers the Adak harbor area. It must be of sufficient resolution to provide useful flooding forecasts and accurately model wave dynamics at the tide gauge. Evaluation of several candidate forecast model C grids showed that only the inner parts of Kuluk Bay, and Sweeper Cove itself, had a substantial impact on wave dynamics at the tide gauge in the inner harbor. Thus, the forecast model C grid has a substantially smaller extent than the reference grid.

To further optimize the number of grid nodes and time step requirements, grid node spacing varies within each forecast model grid (Figure 6). Selectively using a larger node spacing over the deepest regions of the grids in the A and C grids allowed a somewhat longer model time step that still satisfied the CFL condition for stability. It also reduced the total number of nodes in each grid, reducing the computational intensity of the model. The B grid used a closer grid spacing to cover Kagalaska Strait, a narrow passageway into the Adak harbor area that was difficult to correctly model at typical B-grid resolutions.

4 Model Validation and Stability Testing

The model testing process is intended to ensure that the model meets two major requirements that make it usable as part of an operational forecast system. First, the model must accurately predict the actual wave dynamics at the location. Second, the model must be numerically stable for all plausible event source scenarios.

To validate model accuracy, we compare forecast model results with reference model results and tide gauge measurements for several historical tsunami events. To validate numerical stability, we use a suite of large synthetic earthquake source scenarios, as well as a very small (no-wave) scenario. These events are "synthetic" in the sense that they do not represent tsunamis that have happened, but can be viewed as possible worse case scenarios.

4.1 Model validation

As discussed above, Adak has a substantial tsunami history with several tide gauge records available. To test the accuracy with which the model reproduces actual wave dynamics, we compare results produced by the reference and forecast models at the Adak tide gauge location with the tide gauge record of the event.

Figures 7-17 summarize these comparisons, showing maximum amplitudes in the C grid for the reference and forecast models, and a time series at the tide gauge location for each model and the tide gauge record where available. Raw data recorded at the tide gauge were processed through a low-pass Butterworth filter to remove the tide signal. For comparison purposes, the maximum amplitude diagrams are plotted with the same scale and extent, but the forecast model grid covers a smaller area.

In general, comparison is good between the model results and the tide gauge measurements. Wave arrival time comparisons are generally very good. For later waves, several hours after the start of the model run, the forecast model sometimes reports somewhat smaller amplitudes than the reference model. For relatively small events, where recorded maximum amplitudes are less than 15 cm, both models have poorer agreement with the actual tide gauge records, probably because the background noise was relatively stronger in these events.

4.2 Stability testing

To evaluate the stability of the model under a wide range of conditions, the model was tested using a suite of extremely large and small hypothetical source scenarios. Nineteen large source scenarios equivalent to a Mw 9.4 earthquake were used (Table 3). These sources were constructed from the combination of twenty unit sources (a region of 1000×100 km) with a slip (scaling factor) of 30 m. These sources were located along all of the Pacific Ocean subduction zones covered by NOAA's propagation database. Figure 18 shows the time series results at Adak.

The largest amplitude scenarios (acsz_16_25 and acsz_6_15) both result from earthquakes along the Aleutian Subduction Zone immediately adjacent to Adak. These scenarios produce extremely large waves, up to 10-m maximum amplitude, and extensive inundation in the Adak area (Figure 19), but examination of the model output shows that the model remained stable, and continued to produce physically plausible results. In addition to stability with extremely large waves, the model was also validated to produce correct results with very small input waves along the open boundaries of the A grid. In this situation, the model is expected to also output little or no waves; a numerically unstable model might produce ringing or increasing amplitudes in this situation. The Adak forecast model was tested in this "no-wave" case by using a Mw 7.0 earthquake along the East Philippines Subduction Zone (0.18-m slip on source epsza0). In the Adak area, this scenario produces waves less than 0.2 cm amplitude in the propagation data. Resulting waves in the forecast model grids remained under 0.6 cm.

The runtime requirement of a forecast model is that it consumes no more than 10 min of CPU time for a 4-hr simulation. In all the numerical tests, the present forecast model meets this requirement by completing a 4-hr simulation within 3.6 min. By comparison, the reference model required approximately 1.4 hours for the same events. All these computations were performed on a single Intel Xeon processor at 3.6 GHz.

5 Conclusions

A tsunami forecast model covering the Adak, Alaska area has been created for inclusion into SIFT, NOAA's operational tsunami forecast system. This model is capable of forecasting wave amplitudes, arrival time, and flooding areas at Adak for a tsunami event through a 10-hr simulation. The model grids are derived from a compilation of the best available bathymetry for the region. The model has been validated against historical events. Reasonable agreement between tide gauge measurements and model predictions, as well as between the forecast and reference models, is observed in these events. Stability of the forecast model was tested with 19 Mw 9.4 synthetic tsunami scenarios originating from unit source combinations around the Pacific basin. The forecast model remained stable in all these tests. This study further notices that severe flooding can be caused in Adak if a mega-tsunami is generated in the Aleutian Subduction Zone immediately adjacent to this area.

The result is a reliable component of the growing forecast system. It expands the forecast system coverage in the Aleutian Islands. In a real-time forecast situation, model results at this remote location will be valuable for protecting lives and property in Adak, as well as for model-data comparisons to improve forecasts in other parts of the Pacific.

Acknowledgement

Great appreciation goes to Christopher Chamberlin for his early works on the development of the present model. The authors thank Kelly Stroker of NGDC for providing tide gauge records for older historical events, and Michael Dunlap and Lindsey Wright for editing and comments.

Funding for this publication and all works leading to the development of a tsunami forecast model for Adak was provided by NOAA. This publication was partially funded by the Joint Institute for the Study of the Atmosphere and Ocean (JISAO) under NOAA Cooperative Agreement No. NA10OAR4320148 and NA08OAR4320899, JISAO Contribution No. 2126. This is PMEL Contribution No. 3376.

	Harbor	183.60 - 183.33	1.2''	811		183.46 - 183.335	$3.15''^{3}$	149	
Minimum offshore depth (m)					2.0				2.0
Water depth for dry land (m)					0.1				0.1
Friction coefficient (n^2)					0.0009				0.0009
CPU time for a 4-hr simulation ⁴					$1.4~{\rm hr}$:	$3.6 \min$

Table 2: MOST setup of the reference and forecast models for Adak, Alaska.

¹These are average cell sizes. Cell sizes in the forecast model A grid vary between 1.5'-1.75' in the longitude direction, and 1'-1.5' in the latitude direction. See Figure 6 for details.

 $^{^{2}}$ Cell sizes in the forecast model B grid vary between 12"–20" in the longitude direction. Cell sizes are constant in the latitude direction.

³Cell sizes in the forecast model C grid vary between 3"-4" in the longitude direction. Cell sizes are constant in the latitude direction.

⁴Computations were performed on a single Intel Xeon processor at 3.6 GHz, Dell PowerEdge 1850.

C Forecast Model Testing

Authors: Lindsey Wright and Liujuan Tang

C.1 Purpose

Forecast models are tested with synthetic tsunami events covering a range of tsunami source locations and magnitudes. Testing is also done with selected historical tsunami events when available.

The purpose of forecast model testing is three-fold. The first objective is to assure that the results obtained with NOAA's tsunami forecast system, which has been released to the Tsunami Warning Centers for operational use, are identical to those obtained by the researcher during the development of the forecast model. The second objective is to test the forecast model for consistency, accuracy, time efficiency, and quality of results over a range of possible tsunami locations and magnitudes. The third objective is to identify bugs and issues in need of resolution by the researcher who developed the Forecast Model or by the forecast software development team before the next version release to NOAA's two Tsunami Warning Centers.

Local hardware and software applications, and tools familiar to the researcher(s), are used to run the Method of Splitting Tsunamis (MOST) model during the forecast model development. The test results presented in this report lend confidence that the model performs as developed and produces the same results when initiated within the forecast application in an operational setting as those produced by the researcher during the forecast model development. The test results assure those who rely on the Adak tsunami forecast model that consistent results are produced irrespective of system.

C.2 Testing Procedure

The general procedure for forecast model testing is to run a set of synthetic tsunami scenarios and a selected set of historical tsunami events through the forecast system application and compare the results with those obtained by the researcher during the forecast model development and presented in the Tsunami Forecast Model Report. Specific steps taken to test the model include:

- 1. Identification of testing scenarios, including the standard set of synthetic events, appropriate historical events, and customized synthetic scenarios that may have been used by the researcher(s) in developing the forecast model.
- 2. Creation of new events to represent customized synthetic scenarios used by the researcher(s) in developing the forecast model, if any.
- 3. Submission of test model runs with the forecast system, and export of the results from A, B, and C grids, along with time series.
- 4. Recording applicable metadata, including the specific version of the forecast system used for testing.

- 5. Examination of forecast model results from the forecast system for instabilities in both time series and plot results.
- 6. Comparison of forecast model results obtained through the forecast system with those obtained during the forecast model development.
- 7. Summarization of results with specific mention of quality, consistency, and time efficiency.
- 8. Reporting of issues identified to modeler and forecast software development team.
- 9. Retesting the forecast models in the forecast system when reported issues have been addressed or explained.

Synthetic model runs were tested on a DELL PowerEdge R510 computer equipped with two Xeon E5670 processors at 2.93 Ghz, each with 12 MBytes of cache and 32GB memory. The processors are hex core and support hyper threading, resulting in the computer performing as a 24 processor core machine. Additionally, the testing computer supports 10 Gigabit Ethernet for fast network connections. This computer configuration is similar or the same as the configurations of the computers installed at the Tsunami Warning Centers so the compute times should only vary slightly.

C.3 Results

The Adak forecast model was tested with NOAA's tsunami forecast system version 3.2. The propagation database used during development was dated in 2010.

The Adak, Alaska forecast model was tested with four synthetic scenarios and one historical tsunami event. Test results from the forecast system and comparisons with the results obtained during the forecast model development are shown numerically in Table C1 and graphically in Figures C1 to C4. Results show that the minimum and maximum amplitudes and time series generated from SIFT agree with those obtained during the forecast model development. The model run time (wall clock time) was 8.92 minutes for 9.99 hours of simulation time, and 3.56 minutes for 4.0 hours. This run time is within the 10 minute run time for 4 hours of simulation time and satisfies time efficiency requirements.

A suite of synthetic events was run on the Adak forecast model. A slip of 30 m was used during testing rather than the standard 25m to mirror the stability tests used during model development for comparison purposes. The modeled scenarios were stable for all cases tested and all four scenarios produced wave heights greater than 100 cm. The maximum and minimum values of both synthetic and historical events obtained during development show excellent agreements with the results obtained from the forecast system. The Adak reference point used for the forecast model development is the same as what is deployed in the forecast system, so the results can be considered valid for all cases studied.

Figure C1: Response of the Adak forecast model to synthetic scenario ACSZ 56-65 (α =30 m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

Figure C2: Response of the Adak forecast model to synthetic scenario CSSZ 89-98 (α =30 m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

Figure C3: Response of the Adak forecast model to synthetic scenario NTSZ 30-39 (α =30 m). Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

Figure C4: Response of the Adak forecast model to the 2006 Kuril tsunami. Maximum sea surface elevation for (a) A grid, (b) B grid, (c) C grid. Sea surface elevation time series at the C-grid warning point (d).

Table C1: Table of maximum and minimum amplitudes (cm) at the Adak, Alaska warning point for synthetic and historical events tested using SIFT 3.2 and obtained during development.
